In the areas where it occurs, the Dipterocarp family, with 19 genera and nearly 400 species, fills the place in timber production that is occupied by softwoods, oaks, and other familiar species in the North Temperate zone. This Indo-Malayan family extends eastward into New Guinea and the Philippines, and two genera occur to the west in the Seychelles Islands and in tropical Africa (21). The Dipterocarps are made up mainly of species that are noted for producing very large trees, often in nearly pure stands (2).

The genus *Dipterocarpus*, to which *apitong* belongs, includes about 70 species of large trees. Eleven are found in India, 5 in Ceylon, 15 in the Philippine Islands where they rate as the most abundant structural timber, 14 or more in Borneo (12), and some 30 others in the Malay Peninsula and the Indian Archipelago (4, 5, 14, 21, 31).

1 Maintained at Madison, Wis., in cooperation with the University of Wisconsin.
2 Underlined numbers in parentheses refer to the list of numbered references at the end of the article.
Apitong, as known commercially, may be the product of not less than 15 species of the genus *Dipterocarpus* (1). The most common species are *D. grandiflorus* Blanco (= *D. tuberculatus* Roxb.), *D. lasiopodus* Perkins, and *D. vernicifluus* Blanco (1, 17).

In addition to apitong, which is a common name in the Philippines, a number of other trade and vernacular names are often applied to these woods. These include eng in India and England (2, 21), gurjun in Burma, keruing in the Malay Peninsula, hora in Ceylon, and yang in Siam (4, 5, 34).

**The Tree**

*Dipterocarpus grandiflorus* Blanco (= *D. tuberculatus* Roxb.) may be considered as a typical species of the group of woods called apitong. It is one of the most generally known and widely distributed.

**Size**

The trees may attain a height of 50 to 135 feet, often with 50 to 90 feet of clear, straight, cylindrical bole before the first branches. Girths of 8 to 15 feet and diameters up to 90 inches have been reported. The trees have comparatively small buttresses (1, 4, 5, 14, 21).

**Leaves**

The deciduous (8) leaves are leathery and smooth (30).

**Flowers**

The fragrant flowers are white or pink in color (31).

**Fruit**

The fruit is one-celled with two large outwardly curved wings (31).

**Bark**

The bark may be 3 to 4 inches thick, brittle, and light gray to dark brownish gray. It sheds off in large scroll-shaped plates and bears many corky pustules; the inner bark is reddish. Resin used for varnish, torches, and boat caulking exudes when the 1/2-inch inner bark is cut. The ends of the logs tend to be resinous and "tacky" (4, 5, 14, 31).
The Wood

The woods of the different species called apitong are so similar that it is difficult to distinguish one species from another (26).

Color

The sapwood, 3/4 to 3 or more inches in thickness, may be two-zoned; the outer zone may have a creamy-yellow, gray, or reddish-white color that shades into reddish-purple or brown (4, 2). The sapwood tones into the darker reddish- or purplish-brown heartwood, which darkens on exposure (4, 2, 14, 15, 21).

Grain, Texture, and Figure

Apitong wood may notably have fairly straight grain, but it may also be shallowly interlocked or cross-grained. Its even texture is fine to rather coarse (4, 2, 10, 14, 21, 26, 34).

Luster

Apitong is not a lustrous wood (15, 26).

Odor and Taste

The wood has a slightly pleasant resinous odor but no distinct taste (11, 14, 15, 26).

Weight

The weight of apitong, depending on its moisture content, ranges from 36 to 66 pounds per cubic foot with a usual range of 40 to 57 pounds (4, 2, 2, 12, 13, 21, 26).

Specific gravity values from 0.60 to 0.86 have been reported (1, 14, 15, 21, 26).

Mechanical Properties

Strength values of apitong determined on material from different localities in the Philippines varied considerably. The strongest wood was that with the highest density (1, 7). Test data from some early Philippine tests (6) have been tabulated in table 1, which lists values for some properties of green and

1Table prepared by John T. Drow, Timber Mechanics Division, U. S. Forest Products Laboratory.

3Data on air-dry material from same source as data for green material but adjusted from 17 to 12 percent moisture content on the basis of the usual exponential relationship, assuming an "intersection point" of 25 percent moisture content.

4Shrinkage data are approximate, representing the sum of shrinkage values from green to air-dry and air-dry to oven-dry, as reported in Phil. Bur. For. Tech. Bull. No. 7, Appendix 6.

5Load to imbed a 0.144-inch steel ball to 1/2 its diameter.

Report No. R1920
air-dry material. These data were obtained from specimens of the sizes used for Forest Products Laboratory tests. They have been converted from metric system units and adjusted to 12 percent moisture content to make them comparable to data available on familiar United States species. Other test data from India, Malaya, and the Philippines have been reported elsewhere but are based on specimens of different sizes with different moisture content values or are in different units (10, 13, 21, 26, 29).

**Seasoning and Shrinkage**

Comprehensive seasoning information is not available for apitong. The range of variation in density and resin content of the material sold in world markets as apitong is considerable. It is believed, however, that with the careful use of modern drying methods apitong can be adequately seasoned, in spite of the fact that it has had a reputation for being slow to dry and somewhat refractory with notable tendencies to warp, check, split, and collapse (4, 5, 21). Air seasoning (2) or air seasoning prior to kiln drying have both been used with this material.

The British Forest Products Research Laboratory has recommended relatively mild treatment for apitong, starting with temperatures of 110° or 120° F. and 65 percent relative humidity (Schedules Nos. 4 and 5, Leaflet No. 42, "Kiln Drying Schedules," 1949). The U. S. Forest Products Laboratory in its 1951 "Schedules for the Kiln Drying of Wood" (Forest Products Laboratory Report No. D1791) lists as a generally applicable mild schedule, T5-21, which has been suggested for use with green apitong. Schedule T5-C2 in this report would provide a more severe schedule if conditions appeared to warrant it.

As an effective general procedure for minimizing warping, a sticker spacing of not over 18 inches, with all stickers in vertical alinement, and weighting down of the top of the pile has been used.

Shrinkage figures recorded (26) for apitong are:

**Workability**

Working characteristics vary considerably among the different species of Dipterocarpus and even within the same species, as influenced by growth conditions. The woods are generally considered as moderately difficult to work. The presence of silica (4, 5) and gum may give some trouble from blunting of cutting edges or clogging of saws (2, 4, 5, 34). A good finish and polish, however, can be obtained, especially in thoroughly dried material (14, 21). Exceptionally resinous material is troublesome, for example, in
flooring (4, 5), and in the tropics some staining and corrosion have been reported where the wood was in contact with iron (4, 5).

Durability

Dipterocarpus species are rated as only moderately durable in exposed positions (21). For example, untreated railway ties in India lasted only 4 to 5 years and house posts only about 1 year (21). Woods from these species serve well for interior work, but need preservative treatment if used in contact with the ground. They absorb preservatives readily, however, even with open-tank treatment (4, 5, 14). The heartwood of apitong has been reported as resistant to dry-wood termites and powder post beetles (21).

Defects

Heart checks or shakes, oil shakes, end splits, and surface checks sometimes occur or develop during seasoning of apitong (4, 5). Except for the fact that the sapwood is not decay resistant and is attacked by beetles (12), these woods are comparatively free from defects in the logs. The logs, however, should be removed from the woods as soon as possible after the trees are felled. Resin sometimes exudes over the surface of sawn material and a dulling effect on the cutting edges of woodworking tools has been noted (12).

Uses

Apitong is used in construction where hard and heavy timber is required. Its uses include "posts above stumps," beams, joists, rafters, partitions, flooring, mine props, bridges and wharves, poles and railway ties (with preservative treatment), wagon beds, automobile framing, framing of barges and lighters, boats, carts, boxes, railroad cars, and medium-grade furniture (2, 21, 26).

Availability

Apitong is reported as one of the most abundant structural timbers found in good sizes in the Philippines. Volumes of 1,000 to 14,000 board feet per acre have been reported (35).

Structure

Growth rings are not distinct. Pores tend to be rather evenly distributed, rounded in shape, open, and somewhat isolated. Rays are of two sizes (2) but appear to be few in number and narrow. Resin ducts are diffusely scattered and surrounded by bands of parenchyma (14, 26).
Minor Products

Considerable quantities of oleoresin (minyak keruing) are contained in the wood. The resin may exude over the ends of logs and is sometimes collected in hollows hacked in the tree trunks. It is used for caulking boats and for medicine (12).
